**Abstract.** The Tenthredinoidea is the most diverse superfamily of non-apocritan Hymenoptera. It is also one of the largest herbivorous groups within the order, some species having substantial economic impact. Until very recently, no comprehensive phylogenetic analyses of the superfamily had been undertaken. This paper presents the largest morphological dataset assembled so far for elucidating the phylogeny of the Tenthredinoidea. In total, 129 taxa were scored for 146 characters from the adult head, thorax, wings and ovipositor apparatus. The emphasis of the taxon sample is on Tenthredinidae (104 terminals), which is by far the largest family in the Tenthredinoidea. The results of the cladistic analyses confirm the monophyly of the Tenthredinoidea, the first split being between the Blasticotomidae and the remaining families (Tenthredinoidea s. str., also monophyletic), and the monophyly of all families except Tenthredinidae. The analyses fail to consistently retrieve any of the six currently recognised subfamilies within Tenthredinidae, although core clades of Heterarthrinae, Nematinae, Selandriinae and Tenthredininae are often supported. Diprionidae are placed inside the Nematinae under some weighting conditions. The failure to corroborate the tenthredinid subfamilies might be ascribed to an insufficient character/terminal ratio, but also to problems with the existing classification. Inclusion of characters from the male genitalia and the larval stages as well as molecular data currently being assembled will hopefully lead to a more robust classification of the Tenthredinidae in the future.

Received 23 October 2014, accepted 26 January 2015, published online 11 June 2015

## Introduction

The Tenthredinoidea, or true sawflies, are the most diverse lineage of non-apocritan Hymenoptera. The most recent comprehensive compilation reported ~7500 described species in six families and close to 600 genera (Blank *et al.* 2012). Unlike most Hymenoptera, the larvae of Tenthredinoidea are exclusively herbivorous, carnivory having been observed only in a few adults (Jervis and Vilhelmsen 2000). As herbivores, sawfly larvae might have substantial impact on vegetation, in some cases causing serious damage (e.g. Diprionidae). Most sawfly larvae are simple external feeders, resembling typical lepidopteran caterpillars in lifestyle, but within the superfamily more intricate interactions with host plants have repeatedly evolved (e.g. leaf rolling, leaf mining, gall formation; see Gauld and Bolton 1996).

Currently, six subfamilies are recognised in Tenthredinidae (Taeger *et al.* 2010): Allantinae, Blennocampinae, Heterarthrinae, Nematinae, Selandriinae and Tenthredininae. Previously widely recognised subfamilies include Dolerinae and Susaninae, but they are presently included in Selandriinae and Nematinae, respectively. Susaninae, comprising only the small genus *Susana* (10 spp.; Taeger *et al.* 2010), have indeed been repeatedly retrieved as a basal lineage within the Nematinae

in molecular analyses (Nyman *et al.* 2006, 2010; Malm and Nyman 2015; Prous *et al.* 2014).

The tenthredinid subfamilies are mostly defined by combinations of characters from the venation of the forewing (Benson 1952; Goulet 1992). Anyone who has attempted to identify a tenthredinid sawfly has had to deal with an often confusing entry key with characters difficult to visualise, unless properly illustrated, and subfamilies keying out multiple times. Perhaps the most useful key is by Goulet (1992), covering the genera of sawflies in Canada and Alaska, which requires 13 couplets to deal with seven subfamilies of Tenthredinidae (including Susaninae). Only the Tenthredininae key out once, the remaining subfamilies occurring twice except the Nematinae, which make a total of five appearances, including the Susaninae.

Within the last two decades, there has been a surge in papers dealing with the higher-level phylogeny of the Hymenoptera, either focusing on the basal lineages or across the entire order. The culmination has been the recent outputs from the US NSF-funded Hymenoptera Assembling the Tree of Life project (HymAToL) and spinoffs (Vilhelmsen *et al.* 2010; Heraty *et al.* 2011; Sharkey *et al.* 2012; Klopstein *et al.* 2013). These analyses dealing specifically with the basal symphytan

<i>Tenthredopsis ornata</i> (Ten)	
<i>Zaschonyx montana</i> (Ten)	

grade of Hymenoptera (e.g. Vilhelmsen 1997, 2001; Schulmeister *et al.* 2002; Schulmeister 2003a; Ronquist *et al.* 2012; Malm and Nyman 2015) have placed the Tenthredinoidea as either the second or third lineage to branch off from the base of the hymenopteran tree. There is thus no doubt that the superfamily branched off before the evolution of the parasitoid–carnivorous lifestyle displayed by the majority of the Hymenoptera. The Tenthredinoidea retains the ancestral herbivorous lifestyle of the order (see Vilhelmsen and Turrisi 2011), unlike other major herbivorous lineages within Hymenoptera (e.g. bees, fig wasps, gall wasps) which evolved from carnivorous or parasitoid ancestors.

In contrast to the recent advances in resolving especially basal hymenopteran relationships at the superfamily level, there have until very recently not been any comprehensive studies targeting the phylogeny of the Tenthredinoidea. Even the analyses with the largest samples from the superfamily (e.g. Schulmeister 2003a; Ronquist *et al.* 2012) are substantially under-represented with regards to tenthredinoids, especially the largest family, the Tenthredinidae. Nyman *et al.* (1998, 2000, 2006, 2010) performed pioneering molecular analyses on the subfamily Nematinae to unravel their phylogeny and co-evolution with their host plants; Leppänen *et al.* (2012, 2013) similarly explored the leaf-mining Heterarthrinae. Isaka and Sato (2014) did a molecular phylogeny of mostly Palaearctic Selandriinae and estimated the time of origin and initial diversification for the subfamily to the Early Cretaceous.

Recently, Weltz and Vilhelmsen (2014) compiled a dataset of ovipositor system characters also with emphasis on Nematinae. However, they did not have enough characters to obtain satisfactorily resolved and robust results. Better results for Nematinae were obtained by Prous *et al.* (2014), who employed three molecular markers and revised the genus classification for the subfamily. The predominantly Australian–South American family Pergidae was subjected to a combined analysis by Schmidt and Walter (2014), but the rest of the Tenthredinoidea were inadequately sampled for elucidating relationships within the superfamily.

Nevertheless, some relationships at the higher level are repeatedly retrieved. The Tenthredinoidea are always well supported, and the basal split is almost always (but see Sharkey *et al.* 2012) between the Blasticotomidae, a small and rare family of fern-feeders, and the rest, the Tenthredinoidea s. str. (Vilhelmsen 2001). Within the latter, the clade Argidae + Pergidae is usually well supported. The Cimbicidae + Diprionidae + Tenthredinidae frequently form a clade, although Vilhelmsen (2001) placed the Cimbicidae as sister to Argidae + Pergidae. The Cimbicidae + Diprionidae + Tenthredinidae are not consistently resolved, the Cimbicidae + Diprionidae sometimes forming a monophylum (e.g. Schulmeister 2003a; Klopstein *et al.* 2013; Malm and Nyman 2015), sometimes not (Heraty *et al.* 2011; Ronquist *et al.* 2012). Significantly, all analyses except Boevé *et al.* (2013) failed to retrieve the Tenthredinidae as monophyletic, even with a small taxon sample (e.g. Heraty *et al.* 2011); usually, representatives of the genus *Athalia* fall outside the family.

Two studies have recently been published by Boevé *et al.* (2013) and Malm and Nyman (2015), the first to include a

**Table 2. Character list***Head*

1. *Eyes ventrally*: (0) at most slightly converging (Fig. 1A–E); (1) distinctly converging ventrally, reaching medially of lateral margins of clypeus (Fig. 1F).
2. *Dorsal tentorial pit*: (0) indistinct, continuous with ventral groove to torulus (Fig. 1A, D, F); (1) distinct circular pit separated from torulus by raised cuticle (Fig. 1B, C, E).
3. *Epistomal sulcus*: (0) absent or weakly developed, without corresponding internal ridge (Fig. 1A, B, D, F); (1) present, distinct, with ridge (Fig. 1C, E).
4. *Anterior margin of clypeus*: (0) more or less straight (Fig. 1A–C, E); (1) deeply incurved (Fig. 1D, F).
5. *Postocular pit*: (0) absent (Fig. 2A, C, D); (1) small pit immediately posterior to eye present ventrally (Fig. 2B).
6. *Occipital carina laterally*: (0) absent (Fig. 2B, C); (1) present (Fig. 2A, D).
7. *Occipital carina dorsally*: (0) absent (Fig. 2B–D); (1) present, at least reaching occipital sulcus (Fig. 2A).
8. *Ventral head sclerotisation*: (0) absent (Vilhelmsen 2011: fig. 5A); (1) present (Vilhelmsen 2011: fig. 5B).

*Antenna*

9. *Number of antennal segments*: (0) more than nine; (1) nine (Fig. 3A, B, D–F); (2) five to eight (Fig. 3C); (3) four or fewer (ordered).
10. *Lateral projections in males*: (0) absent; (1) present (Fig. 3A).
11. *Pedicellus*: (0) shorter than wide (Fig. 3A, B); (1) 1–1.5× as long as wide (Fig. 3D, F); (2) 1.5× as long as wide or longer (Fig. 3C, E) (ordered).
12. *Third antennomere*: (0) not conspicuously enlarged (Fig. 3A–F); (1) enlarged, comprising at least a third of total length of antenna (Beutel and Vilhelmsen 2007: fig. 2A).
13. *Antennomeres 3 and 4*: (0) 3rd shorter than 4th (Fig. 3A, B); (1) 3rd equal to or, at most, 1.5× longer than 4th (Fig. 3E); (2) 3rd at least 1.5× longer than 4th (Fig. 3C, D, F) (ordered).
14. *Apical antennomeres*: (0) not conspicuously modified (Fig. 3A–F); (1) one or more apical antennomeres forming distinct club.

*Mouthparts*

15. *Labrum, position*: (0) anterior to tips of mandibles (Vilhelmsen 2011: fig. 1A, B); (1) posterior to tips of mandibles (Vilhelmsen 2011: fig. 1C).
16. *Labrum, tormae*: (0) separate apodemes; (1) fused medially, forming continuous bar.
17. *Mandible, profile*: (0) left mandible gradually tapering to apex in lateral view (Fig. 2A, B, D); (1) subdivided, with broad base and abruptly tapered distal part (Fig. 2C).
18. *Left mandible apical teeth*: (0) one; (1) two (Fig. 1C–E); (2) three (Fig. 1A); (3) four (ordered).
19. *Maxilla, number of palpal segments*: (0) six; (1) five or fewer.
20. *Labium, number of palpal segments*: (0) four; (1) three.

*Pronotum*

21. *Length*: (0) pronotum short dorsally of transverse pronotal sulcus (Fig. 4A, D, F); (1) long dorsally of transverse pronotal sulcus (Fig. 4B).
22. *Orientation*: (0) pronotum oblique posterior to transverse pronotal sulcus (Vilhelmsen 2000b: fig. 2A, E, F); (1) vertical posterior to transverse pronotal sulcus (Fig. 4B).
23. *Posterodorsal corner*: (0) without notch (Vilhelmsen 2000b: fig. 2A, E, F); (1) with distinct notch above anterior thoracic spiracle (Fig. 4A–F).
24. *Posterolateral margin*: (0) straight (Vilhelmsen 2000b: fig. 2A, E); (1) with incursion accommodating anterior thoracic spiracle (Fig. 4A–F).
25. *Mesopleural attachment*: (1) pronotum separate from anterior mesopleural margin (Vilhelmsen 2000b: fig. 2A); (1) pronotum articulating with mesopleuron below spiracle (Fig. 4B, D, F); (2) pronotum fused with mesopleuron below spiracle for only short distance (Fig. 4A); (3) pronotum fused with mesopleuron below spiracle for entire distance (ordered).

*Propectus*

26. *Propleuron, dorsal cervical sclerite*: (0) absent or broadly fused with rest of propleuron (Fig. 5B, C); (1) sclerite present, at most attached to propleuron for short distance posteriorly (Fig. 5A, D).
27. *Propleuron, cervical line*: (0) absent (Fig. 5B–D); (1) present, cervical sclerite partly separated from rest of propleuron (Fig. 5A).
28. *Propleuron, propleural sulcus*: (0) absent (Fig. 5B); (1) sulcus and corresponding internal ridge present (Fig. 5A, C, D).
29. *Propleuron, medioventral margins*: (0) entirely separate medially (Fig. 6A, C); (1) abutting medially for at least a short distance (Fig. 6D).
30. *Propleuron, katepisternum*: (0) absent (Fig. 6A, C); (1) present (Fig. 6B, D).
31. *Propleuron, configuration of katepisternum*: (0) adjacent to lateral procoxal articulation (Vilhelmsen 2000b: fig. 17B, C); (1) separate from lateral procoxal articulation (Fig. 6B, D).
32. *Prosternum, laterosternal sclerites*: (0) absent or fused with prosternum (Fig. 6A, C, D); (1) independent sclerite present (Fig. 6B).
33. *Prosternum, anterolateral corner*: (0) separate from the propleuron (Fig. 6B–D); (1) fused with the posteroventral corners of the propleuron (Fig. 6A).
34. *Fore leg, calcar*: (0) anterior fore tibial spur simple, straight (Basibuyuk and Quicke 1995: fig. 2F–I); (1) anterior fore tibial spur curved, bifid (Basibuyuk and Quicke 1995: fig. 2B, E).
35. *Fore leg, inner apical protibial spur*: (0) absent; (1) present.
36. *Fore leg, tips of apical protibial spurs*: (0) pointed and sclerotised (Basibuyuk and Quicke 1995: fig. 2H, I); (1) blunt and membranous (Basibuyuk and Quicke 1995: fig. 2F, G).

*Mesonotum*

37. *Length of median mesoscutal sulcus*: (0) short, terminating at least 0.75 own length from scutellar sulcus (Fig. 7A–C); (1) distance between posterior end and scutellar sulcus at most 1/2 length of median sulcus (Fig. 7D).
38. *Notauli*: (0) absent or reduced, terminating well before midline of mesoscutum posteriorly (Fig. 7B); (1) fully developed, almost reaching midline posteriorly (Fig. 7A, C, D).

(continued next page)

**Table 2.** (*continued*)

39. *Notauli configuration*: (0) no difference between anterior and posterior part (Fig. 7A, D); (1) anterior part narrow, posterior part wider, with depression (Fig. 7C).
40. *Postscutellum*: (0) absent or reduced (Fig. 7A); (1) present, distinct (Fig. 7C, D).
- Mesopectus*
41. *Postspiracular sclerite*: (0) absent (Vilhelmsen 2000b: fig. 1); (1) present (Fig. 4A–F).
42. *Prepectus*: (0) absent or fused with adjacent sclerite (Fig. 4A); (1) independent sclerite present (Fig. 4E, F).
43. *Anterodorsal part of mesopleuron*: (0) not set off from surrounding part (Fig. 4A–C, F); (1) raised and/or separated by groove, line etc. (Fig. 4D, E).
44. *Posterior thoracic spiracle*: (0) spiracle visible in lateral view (Fig. 4A, F); (1) spiracle concealed in lateral view by mesopleuron (Fig. 4B–E).
45. *Posterior dorsal margin of mesopleuron*: (0) straight in lateral view (Fig. 4D, E); (1) with incursion at posterior thoracic spiracle (Fig. 4A, C, F); (2) with raised flap lateral to spiracle (Fig. 4B) (unordered).
46. *Prospinasternum*: (0) separate from mesopleuron (Vilhelmsen 2000b: fig. 1B, 7A); (1) fused with anterior mesopleural margin (Fig. 4A).
47. *Prospinasternal apodeme*: (0) small or absent (Vilhelmsen 2000b, Fig. 7A); (1) large (Fig. 4A).
48. *Mesopseudosternal sulcus*: (0) absent or weakly developed with no corresponding internal structure (Fig. 4B–F); (1) well developed with corresponding internal ridge (Fig. 4A).
49. *Mesopseudosternal sulcus configuration*: (0) not reaching anterior margin of mesopleuron; (1) extending to anterior margin of mesopleuron (Fig. 4A).
50. *Mesospinasternal apodeme*: (0) absent (Vilhelmsen 2000a: fig. 7D); (1) present, receiving metafurco-mesospinal muscles (Vilhelmsen 2000a: fig. 7C).
51. *Anterior mesofurcal arm*: (0) absent or reduced (Vilhelmsen 2000a: fig. 7D); (1) present, elongate (Vilhelmsen 2000a: fig. 7C).
52. *Lateral mesofurcal arm*: (0) short (Heraty *et al.* 1994: figs 3, 4); (1) elongate, extending towards mesopleuron (Vilhelmsen 2000a: fig. 7C, D).
- Metanotum*
53. *Insertion point of mesoscutello-metanotal muscle*: (0) not on a conspicuous structure (Fig. 8B–D); (1) on ring-like structure medially on anterior metanotal margin (Fig. 8A).
54. *Connection to 2nd phragma*: (0) sclerotised, at most separated by short membranous part (Vilhelmsen 2000a: figs 8A, 11A); (1) separated by extensive membranous area (Vilhelmsen 2000a: figs 9A, 10A).
55. *Lateral metanotal process*: (0) absent or short, blunt; (1) slender, projecting ventrally and/or medially.
56. *Shape of cenchrus*: (0) less than twice as broad as long (Fig. 8B–D); (1) at least twice as broad as long (Fig. 8A); (2) more than three times as broad as long (Vilhelmsen 2000a: fig. 3B) (ordered).
57. *Posterior part of cenchrus*: (0) membranous and inflected, devoid of hooks (Fig. 8B–D); (1) not inflected, hooks extend across entire surface (Fig. 8A).
58. *Apodeme for lateral metanoto-metapleural muscle*: (0) absent or small; (1) present, conspicuous.
59. *Metapostnotum size*: (0) shorter than 1/2 length of T1 (Fig. 8A, C, D); (1) at least as long as 1/2 length of T1 where longest (Fig. 8B).
- Metapectus*
60. *Anepimeron anteriorly*: (0) not expanded, metapleural arm clearly visible (Fig. 9C); (1) expanded anteriorly and dorsally, convex (Fig. 9A); (2) arm elongate and slender, not expanded distally (Fig. 9B, D) (unordered).
61. *Anterior margin of metapleuron*: (0) without apodeme dorsally (Fig. 9B–D); (1) with distinct apodeme ventral to anapleural cleft (Figs 9A, 10A).
62. *Anapleural cleft*: (0) absent (Fig. 9C, D); (1) present (Fig. 9A, B).
63. *Metapleuron configuration with T1*: (0) at most abutting (Fig. 9B–D); (1) fused (Fig. 9A).
64. *Metapleural apodeme*: (0) at most shallow ridge present (Vilhelmsen 2000a: fig. 7B); (1) distinct apodeme present (Vilhelmsen 2000a: fig. 7D).
65. *Metapleuron posteroventral apodeme*: (0) absent (Vilhelmsen 2000a: fig. 7D); (1) present, accommodating posterior pl3-fu3 muscle (Vilhelmsen 2000a: fig. 7C (t24)).
66. *Paracoxal notches*: (0) absent (Fig. 10A–D); (1) present (Vilhelmsen 2000a: fig. 6B).
67. *Paracoxal sulcus and ridge*: (0) curving anteriorly (Fig. 10A, C); (1) curving posteriorly (Fig. 10B, D).
68. *Paracoxal sulcus termination*: (0) at posterior margin of metepisternum (Fig. 10D); (1) in middle of metepisternum (Fig. 10B, C); (2) in metapleural sulcus close to anterior margin of metepisternum (Fig. 10A) (unordered).
69. *Anterior metafurcal arms*: (0) absent or weakly developed (Vilhelmsen 2000a: fig. 7D); (1) well developed (Fig. 10C).
70. *Lateral metafurcal arms*: (0) short (Vilhelmsen 2000a: fig. 7A); (1) well developed, extending laterally (Vilhelmsen 2000a: fig. 7D).
71. *Metathoracic trochantin*: (0) absent; (1) present, receiving muscle (Vilhelmsen 2000a: figs 8B, 11B).
72. *Hind femur length*: (0) shorter than hind tibia (excl. trochantellus); (1) approx. equal to hind tibia.
73. *Preapical hind tibial spurs*: (0) absent; (1) present.
74. *Apical hind tibial spurs*: (0) short, not much longer than apical breadth of tibia; (1) length at least 2× apical breadth of hind tibia.
75. *Hind basitarsus length*: (0) shorter than tarsomeres 2–4; (1) equal to or longer than tarsomeres 2–4.
76. *Hind tarsal pulvilli*: (0) absent from tarsomeres 1 and 2; (1) present on tarsomeres 1–4.
77. *Hind tarsal claw basal lobe*: (0) absent or weakly developed; (1) present, distinct.
78. *Hind tarsal claw*: (0) simple, without additional tooth; (1) bifid.
79. *Hind tarsal claw teeth length*: (0) of subequal length (when bifid); (1) inner tooth much shorter than apical.
- Abdominal T1*
80. *T1 medially*: (0) subdivided by median longitudinal line (Fig. 8A, B, D); (1) fused medially, entire (Fig. 8C).
81. *T1 membranous patch*: (0) small, T1 inner margins subparallel at least anteriorly (Fig. 8A, B); (1) well developed, T1 inner margins diverging for almost entire length (Fig. 8D).

(continued next page)

**Table 2.** (continued)

82. *T1, metalaterophragmal lobe*: (0) absent or weakly developed (Vilhelmsen 2000a: fig. 4A, C); (1) present, distinct (Fig. 8B, C; Vilhelmsen 2000a: fig. 4B, D).

#### Forewing

83. *Subcosta*: (0) at most short transverse vein present; (1) distinct, separate longitudinal vein extending at least half length of costal cell.

84. *Subcosta anterior branch*: (0) entirely absent (Fig. 11A, B); (1) not tubular and/or interrupted (Fig. 11D); (2) tubular, reaching vein C (Fig. 11G) (ordered).

85. *Subcosta anterior branch position*: (0) proximal to M – Sc+R junction (Fig. 11D, G); (1) distal to M – Sc+R junction.

86. *Costal cell in middle*: (0) higher than width of veins C and R combined (Fig. 11D); (1) shorter than or equal to width of veins C and R combined (Fig. 11A, B).

87. *Vein R configuration*: (0) straight throughout (Figs 11A, G, 12C); (1) with distinct bend at cell 1M (Figs 11B, 12E, F).

88. *Cell 1M*: (0) angular anteriorly (Figs 11C, 12A); (1) rounded anteriorly (Fig. 11A).

89. *Vein M junction to Sc+R*: (0) very close to Rs+M junction (Figs 11F, 12A); (1) some distance from Rs+M junction (Figs 11E, G, H, 12E, F).

90. *Veins m and 1m-cu configuration*: (0) more or less parallel (Fig. 12A, B, E); (1) convergent (Fig. 11B, H).

91. *Rs+M proximal part*: (0) more or less straight (Fig. 12B); (1) strongly recurved (Fig. 12C, D).

92. *1st abscissa of Rs*: (0) absent or very short (Fig. 11B); (1) present (Fig. 11A).

93. *Shape of 1st abscissa of Rs*: (0) anterior end more proximal than posterior; (1) posterior end more proximal than anterior.

94. *Abscissa of Rs*: (0) entirely absent as tubular vein between cells 1R and Rs (Figs 11G, H, 12A); (1) present only partly as tubular vein between cells 1R and Rs (Fig. 11D); (2) fully developed, might have bulla (Fig. 12B, D, E) (ordered).

95. *Cross vein 2r*: (0) absent (Fig. 11B–D, F, G); (1) present (Figs 11A, E, H, 12A, D).

96. *Cross vein 2r position*: (0) proximal or opposite 2r-m; (1) distal to 2r-m (Figs 11A, E, H, 12A, D).

97. *Tip of radial cell*: (0) on anterior wing margin (Figs 11D, F, 12F); (1) retracted from anterior wing margin (Fig. 11C); (2) radial cell open (Fig. 11B) (unordered).

98. *Cross vein 2r-m*: (0) absent (Figs 11C, 12C); (1) present (Figs 11D–G, 12D).

99. *Rs - 2r-m/2r-m - 3r-m distance, measured along vein Rs*: (0) Rs to 2r-m longer than 2r-m to 3r-m (Figs 11G, 12E); (1) 2r-m to 3r-m as least as long as Rs to 2r-m (Fig. 11B, D).

100. *1m-cu/Cu1 angle*: (0) veins meeting in angle less than 110 degrees (Figs 11B, H, 12B); (1) veins meeting in angle more than 120 degrees (Fig. 12A, E, F).

101. *Veins 1m-cu and 2m-cu*: (0) inserts on M in different cells (Fig. 11D, F); (1) both insert on M in cell 1RS (Fig. 11C, E, G).

102. *Cross vein 3r-m*: (0) absent; (1) present.

103. *Cu-a insertion*: (0)  $1/2 \times$  cu-a length or more from base of Cu1 (Figs 11A, 12B); (1)  $1/4$  to  $1/2 \times$  cu-a length from base of Cu1 (Fig. 11D); (2)  $1/4$  or less  $\times$  cu-a length from base of Cu1 (Fig. 12A); (3) cu-a in apposition to M (Fig. 11E) (ordered).

104. *Posterior anal vein and cross vein 1a*: (0) entirely absent (Fig. 11C); (1) posterior anal vein absent proximally of 1a (Figs 11B, G, H, 12B); (2) present for short distance proximally and distally (Figs 11E, F, 12F); (3) present along entire length of anterior anal vein (Figs 11A, D, 12A, C–E) (ordered).

105. *Cross vein 1a*: (0) absent (Fig. 12D); (1) present (Figs 11A, D, 12A, C, E).

106. *Cross vein 1a position*: (0) in distal half of anal cell, distal to incursion (Figs 11A, D, 12A, C); (1) in proximal half of anal cell, at incursion (Fig. 12E).

107. *Cross vein 1a configuration*: (0) oblique (Figs 11A, 12A, C); (1) straight (Figs 11D, 12E).

108. *Vein 3a*: (0) curved (Fig. 12B); (1) straight (Fig. 11G, H).

109. *Vein 3a apex*: (0) not divided at apex (Fig. 11G, H); (1) bifid (Fig. 12B).

#### Hindwing

110. *Distal hamuli placement*: (0) en echelon (Basibuyuk and Quicke 1997: figs 5C, 6); (1) aligned (Basibuyuk and Quicke 1997: fig. 5B).

111. *Secondary hamuli*: (0) absent (Basibuyuk and Quicke 1997: fig. 2D); (1) present (Basibuyuk and Quicke 1997: fig. 2C).

112. *Subcosta*: (0) absent (Fig. 13A, B); (1) present.

113. *Cell R1*: (0) entirely closed off by veins (Fig. 13A, C, E, F); (1) open distally, vein R1 incomplete (Fig. 13B, D).

114. *Cross vein 3r-m*: (0) absent (Fig. 13C, D); (1) present (Fig. 13A, B, E, F).

115. *Cross vein m-cu*: (0) absent (Fig. 13C, D); (1) present (Fig. 13A, B, E, F).

116. *Veins 3r-m/m-cu configuration*: (0) 3r-m less than own length away from m-cu (Fig. 13A, B); (1) 3r-m at least own length away from m-cu (Fig. 13F).

117. *Marginal vein*: (0) absent (Fig. 13D); (1) present at least in males (Fig. 13E).

118. *Posterior anal vein*: (0) absent or at least partly reduced (Fig. 13B, D); (1) present, complete (Fig. 13A, C, E, F).

119. *Length of anal cell*: (0) as long as cell 1Cu posteriorly (Fig. 13F); (1) shorter than cell 1Cu (Fig. 13A, C, E).

#### Abdomen

Characters 122–127 have been illustrated and discussed in Weltz and Vilhelmsen (2014).

120. *Pleural region of abdominal terga*: (0) separate from terga s. str. (Vilhelmsen 2001: fig. 5A, B); (1) fused with terga s. str. (Vilhelmsen 2001: fig. 5C).

121. *Abdominal spiracle position*: (0) ventral to membranous subdivision of terga (Vilhelmsen 2001: fig. 5A); (1) dorsal to membranous subdivision of terga (Vilhelmsen 2001: fig. 5B).

122. *T8, anterolateral corners*: (0) without extension; (1) with extension.

(continued next page)

**Table 2.** (*continued*)

123. *T9, anterior flanges*: (0) continuous medially at least through thickened posterior rim; (1) not continuous medially.
124. *Cercus*: (0) length/mid-breadth ratio at most 2; (1) length/mid-breadth ratio between 2 and 5; (2) length/mid-breadth ratio at least 5 (ordered).
125. *Length of cercus/medial length of tergum 10*: (0) at most 0.7; (1) between 0.7 and 1; (2) at least 1 (ordered).
126. *Length of cercus/medial length of tergum 9 + tergum 10*: (0) at most 0.5; (1) between 0.5 and 1; (2) at least 1 (ordered).
127. *Medial length of tergum 10/medial length of tergum 9*: (0) at most 1; (1) between 1 and 2; (2) at least 2 (ordered).
- Ovipositor*
- Characters 128–146 have been illustrated and discussed in Weltz and Vilhelmsen (2014).
128. *Length of 3rd valvula/length of part of 3rd valvula from level of median bridge to posterior end*: (0) at most 1.3; (1) between 1.3 and 1.9; (2) at least 1.9 (ordered).
129. *Banding pattern on 1st and 2nd valvula*: (0) absent; (1) present.
130. *Lamnium of 1st valvula*: (0) comprising at least half of length; (1) comprising slightly less than half of length; (2) comprising short distance distally only (ordered).
131. *Distribution of sawteeth on 1st valvula*: (0) present along at least half of length; (1) present along between half and third of length; (2) present along third of length; (3) present along quarter of length; (4) present for less than quarter of length (ordered).
132. *Serrulae on sawteeth*: (0) absent; (1) present on sawteeth of 1st valvula.
133. *Lateral part of 1st valvula*: (0) without hairs; (1) with hairs.
134. *Ctenidia laterally on 1st valvula*: (0) absent; (1) present on annuli.
135. *Spurettes laterally on 1st valvula*: (0) absent; (1) present on annuli.
136. *Aulax on 1st valvula*: (0) entirely on dorsal margin of 1st valvula; (1) displaced ventrally on medial wall of 1st valvula for less than half of length; (2) displaced ventrally on medial wall of 1st valvula for at least half of length (ordered).
137. *Second valvifer and 3rd valvula*: (0) at least partly separated by membranous area; (1) totally fused.
138. *Second valvifer*: (0) continuous with median bridge at least through weakly sclerotised strip; (1) entirely separated from median bridge by membrane.
139. *Posterodorsal part of 2nd valvifer*: (0) do not project posteriorly of ventral margin of 2nd valvifer; (1) produced posteriorly of ventral margin of 2nd valvifer.
140. *Distal part of dorsal flange*: (0) curving dorsomedially; (1) curving dorsally; (2) more or less straight (unordered).
141. *Anterodorsal parts of 3rd valvulae*: (0) fused/continuous medially; (1) at least slightly separated medially.
142. *Second valvula*: (0) separate from opposite apically; (1) fused with opposite apically.
143. *Lengths of 2nd valvulae*: (0) equal; (1) unequal.
144. *Less sclerotised zones of 2nd valvula*: (0) put together, comprising clearly less than half of length of lamnium; (1) put together, comprising about half of length of lamnium; (2) put together, comprising clearly more than half of length of lamnium (ordered).
145. *Sawteeth on 2nd valvula*: (0) absent; (1) present on dorsal margin.
146. *Annuli of 2nd valvula*: (0) ventral terminations without tufts of hairs; (1) ventral terminations with tufts of hairs.

substantial number of exemplars sampled broadly across the Tenthredinidae. Boevé *et al.* (2013) assembled a dataset comprising 100+ tenthredinid taxa, but only a dozen outgroup taxa to explore the evolution of larval chemical defenses. Furthermore, many genera are represented by more than one terminal (*Monophadnus* by no less than nine), so in total 64 tenthredinid genera are included (Boevé *et al.* 2013: fig. 3). These were sequenced for two mitochondrial and one nuclear gene. This dataset retrieved the Tenthredinidae as monophyletic, but did not reproduce the existing subfamily classification. Interestingly, Heptamelini (*Heptamelus* + *Pseudoheptamelus*) and *Athalia* spp. were placed as successive outgroups to all remaining Tenthredinidae.

Malm and Nyman (2015) have a more balanced taxon sample, including ~80 exemplars of Tenthredinidae, as well as 40 representatives from the other tenthredinoid families. Despite the lower number of tenthredinid terminals, almost as many genera (61) are included as in Boevé *et al.* (2013). With data from nine protein coding genes Malm and Nyman (2015) were able to produce robust results and properly test the subfamily classification of the Tenthredinidae,

something no previous study has accomplished. The subfamilies Nematinae and Tenthredininae are retrieved as well supported, as well as core clades of Allantinae (except *Athalia* spp., *Eriocampa* and *Eusunoxa*) and Selandriinae (except Heptamelini: *Heptamelus* + *Pseudoheptamelus*). More problematic are the Blennocampinae and Heterarthrinae, the latter being placed as two separate clades within the Blennocampinae. Malm and Nyman (2015) even retrieved all Tenthredinidae except Heptamelini as monophyletic, although not with strong support. *Athalia* spp. were sister to all Tenthredinidae except Heptamelini. Consequently, Malm and Nyman (2015) suggested elevating Heptamelini to family status (Heptamelidae).

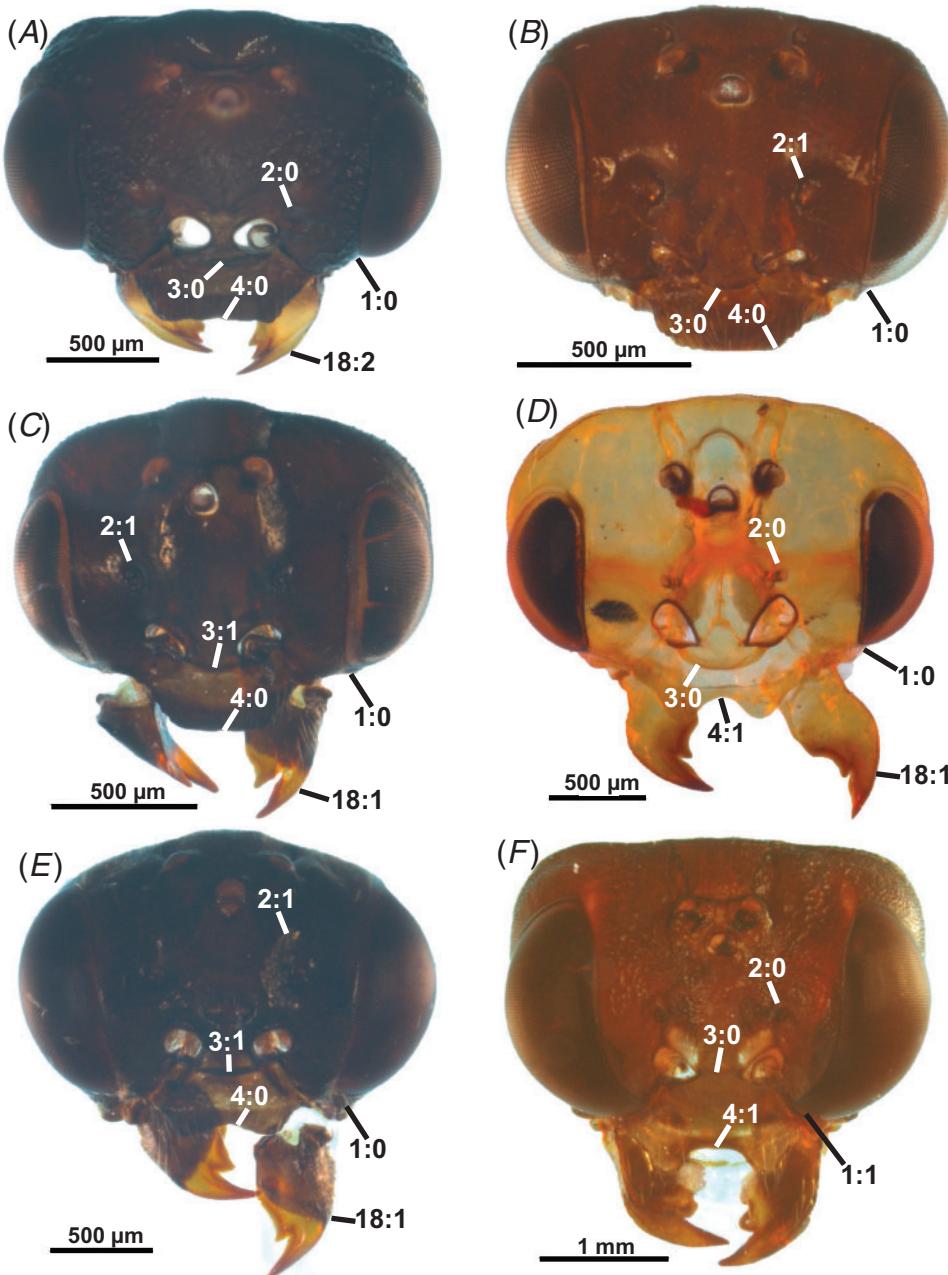

The current study presents the largest taxon sample assembled for exploring relationships across the Tenthredinidae and the placement of the other tenthredinoid families relative to Tenthredinidae. A correspondingly high number of morphological characters have been scored for this endeavour. The aim is to test the existing subfamily classification of the Tenthredinidae and provide a baseline for improving it, as well as revealing characters that might be useful for purposes of identification.

## Materials and methods

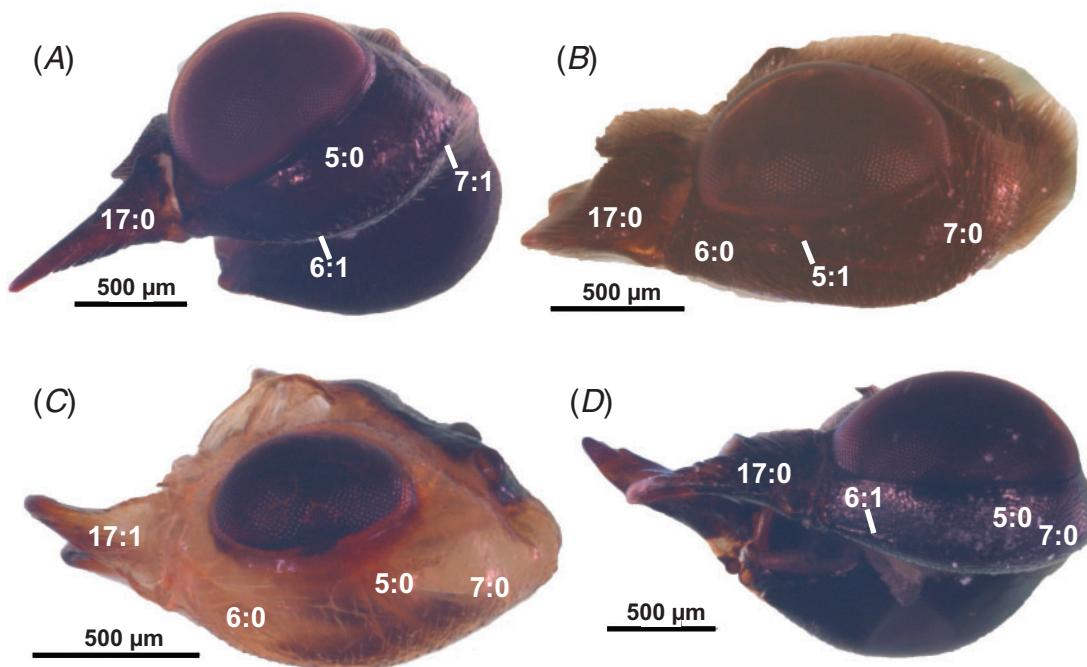

### Material examined

In total, 129 terminals were included in the analyses: five non-tenthredinoid outgroups, three Argidae, three Blasticotomidae, four Cimbicidae, four Diprionidae, six Pergidae and 104

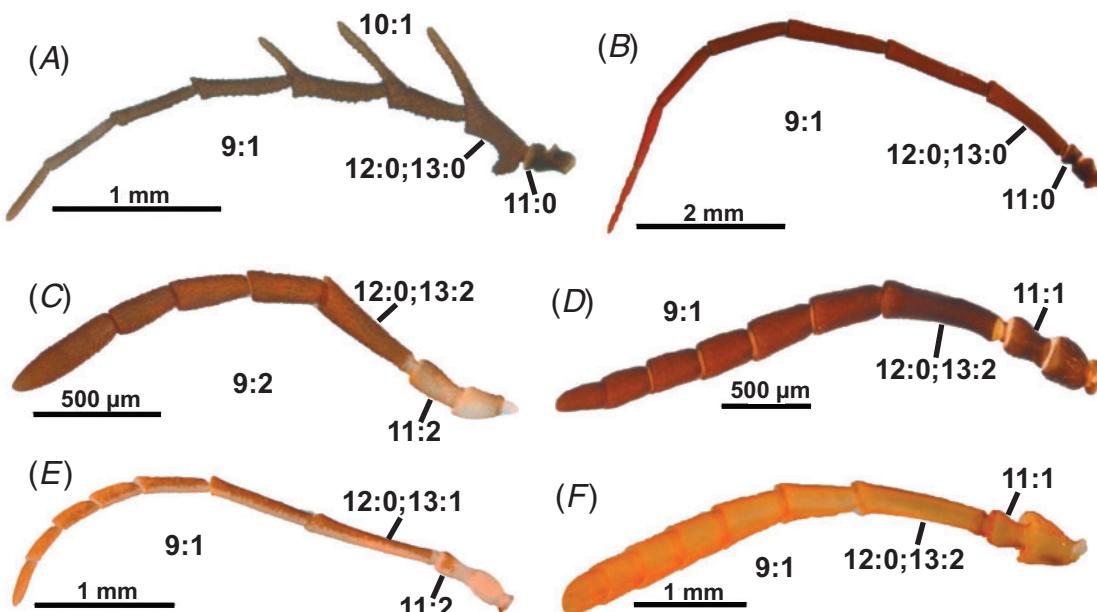

Tenthredinidae. Within the latter, the six subfamilies (according to Taeger *et al.* 2010) were represented as follows: 21 Allantinae, 20 Blennocampinae, 9 Heterarthrinae, 20 Nematinae, 18 Selandriinae and 16 Tenthredininae. The dissected specimens are stored in the Natural History Museum of Denmark, University of Copenhagen.

**Fig. 1.** Anterior view of head of: (A) *Blasticotoma filiceti* Klug, 1834 (Blasticotomidae); (B) *Blennocampa phyllocolpa* Viitasaari and Vikberg, 1985 (Tenthredinidae, Blennocampinae); (C) *Endelomyia aethiops* (Gmelin, 1790) (Tenthredinidae, Heterarthrinae); (D) *Hemichroa australis* (Serville, 1823) (Tenthredinidae, Nematinae); (E) *Aneugmenus padi* (Linné, 1760) (Tenthredinidae, Selandriinae); (F) *Tenthredo scrophulariae* Klug, 1817 (Tenthredinidae, Tenthredininae). Character states indicated by numbers.

**Fig. 2.** Lateral view of head of: (A) *Taxonus agrorum* (Fallén, 1808) (Tenthredinidae, Allantinae); (B) *Phymatocera aterrima* (Klug, 1816) (Tenthredinidae, Blennocampinae); (C) *Pachynematus clitellatus* (Serville, 1823) (Tenthredinidae, Nematinae); (D) *Filacus albipes* (Provancher, 1895) (Tenthredinidae, Tenthredininae). Character states indicated by numbers.

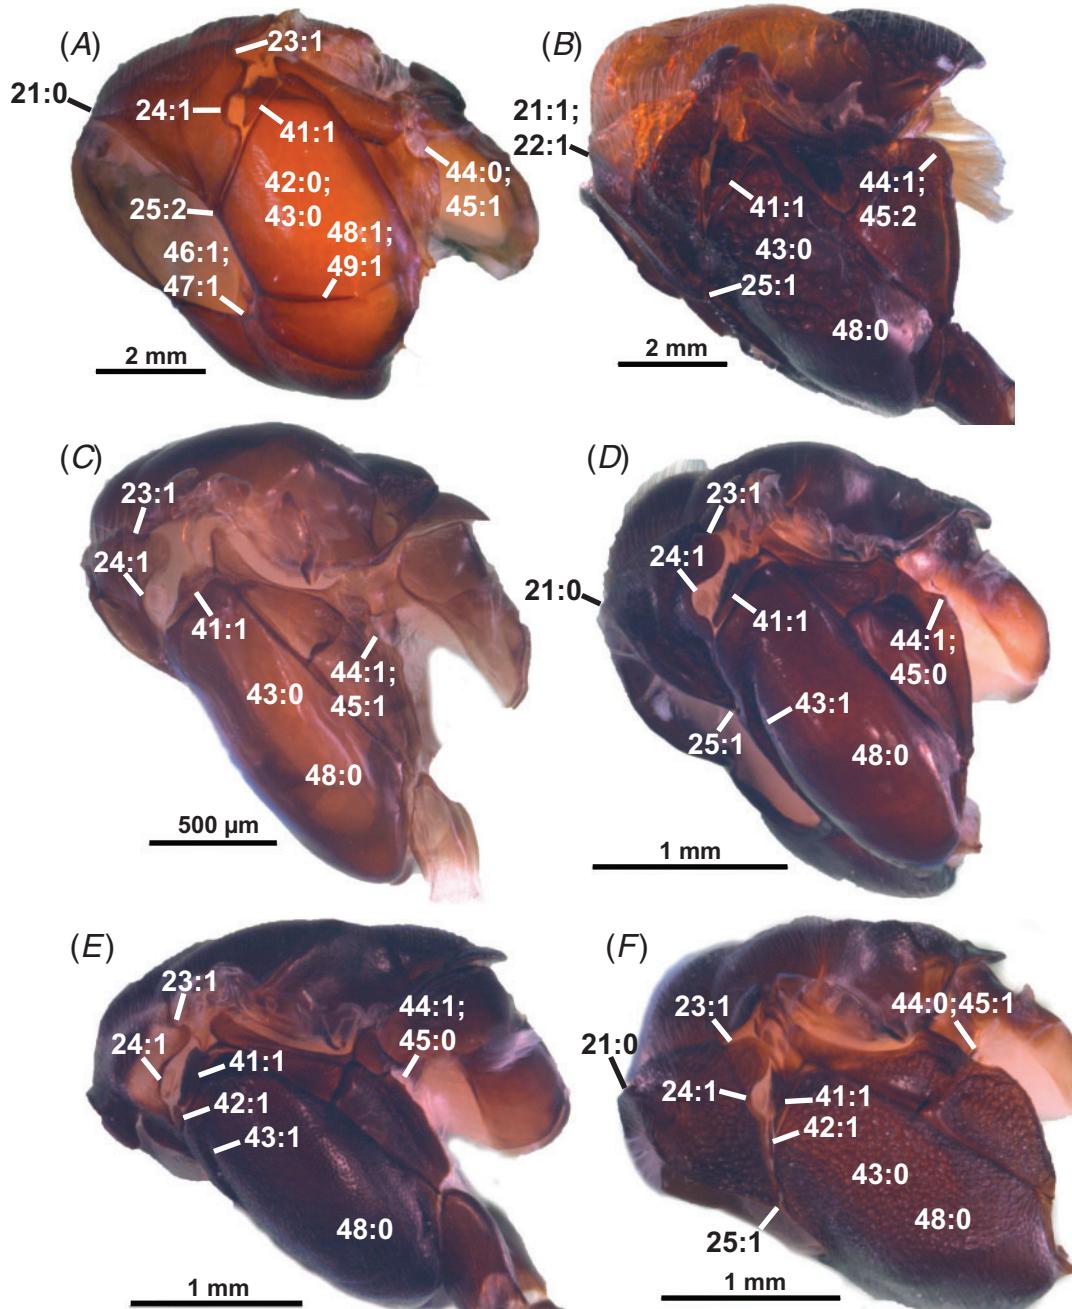

**Fig. 3.** Antennae of: (A) *Cladius pectinicornis* (Geoffroy, 1785) (Tenthredinidae, Nematinae); (B) *Craesus septentrionalis* (Linné, 1758) (Tenthredinidae, Nematinae); (C) *Heptamelus dahlbomi* (Thomson, 1870) (Tenthredinidae, Selandriinae); (D) *Selandria serva* (Fabricius, 1793) (Tenthredinidae, Selandriinae); (E) *Strombocerus delicatulus* (Fallén, 1808) (Tenthredinidae, Selandriinae); (F) *Tenthredo scrophulariae* Klug, 1817 (Tenthredinidae, Tenthredininae). Character states indicated by numbers.

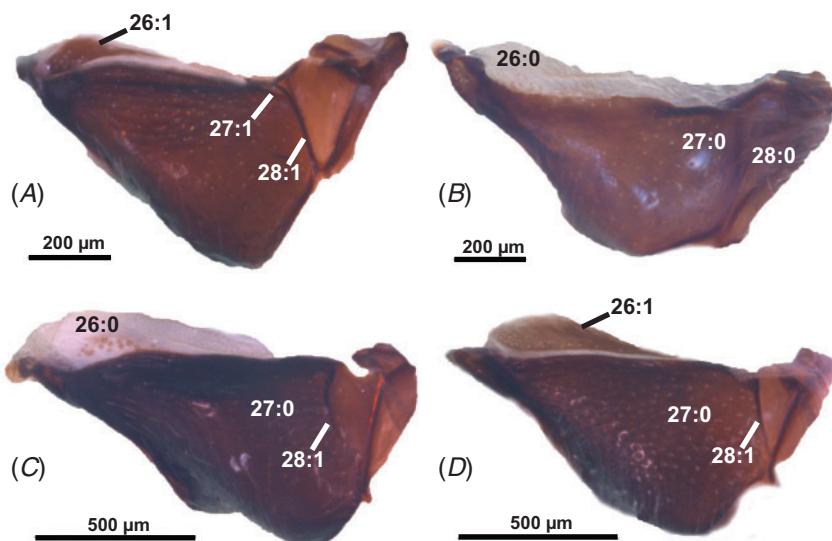

The Tenthredinidae are most diverse in the northern hemisphere, and the majority of the terminals included come from the Palaearctic. However, efforts have been made to also include some of the rarer taxa from the Afrotropical and Neotropical regions. For further details of the material examined, see Table S1 (available as Supplementary Material on the journal website).

#### Dissections, imaging and character scoring

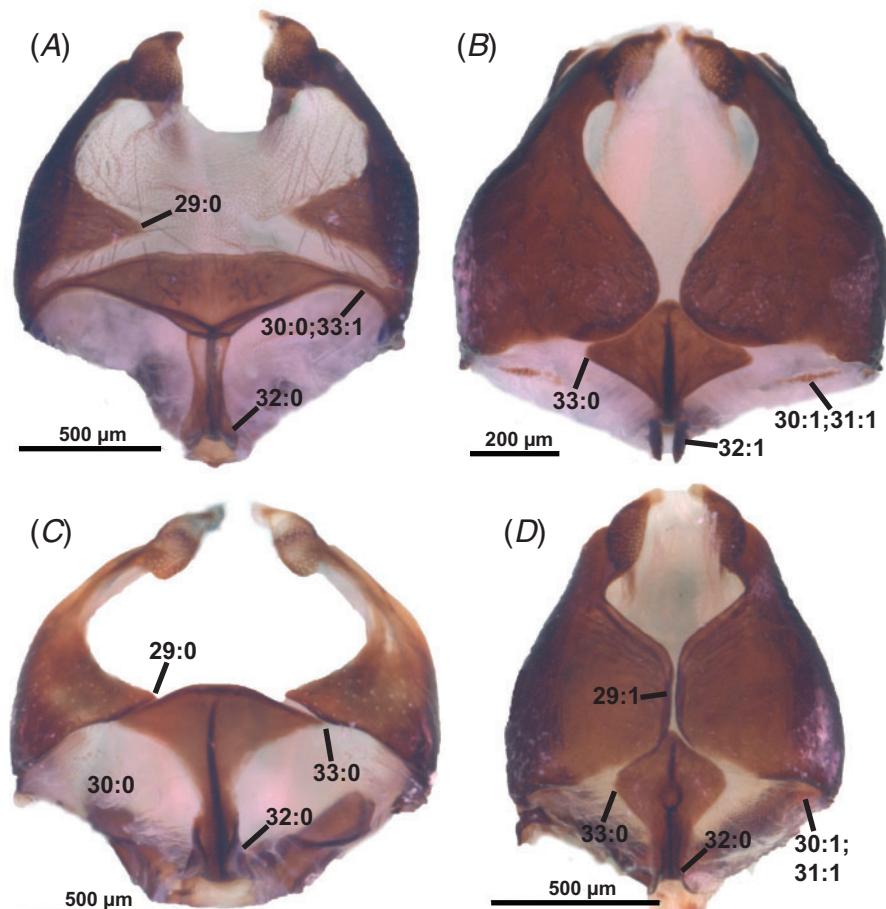

Most specimens were preserved in 70% ethanol before dissection. Dissection and scoring of characters were carried out under a Leica MZ16 APO or Leica M205C dissecting microscope (Leica Microsystems, Wetzlar, Germany). Dissected material was stored and examined in glycerin. Selected features (antennae, labrum, labiomaxillary complex, hind tarsi) were mounted on

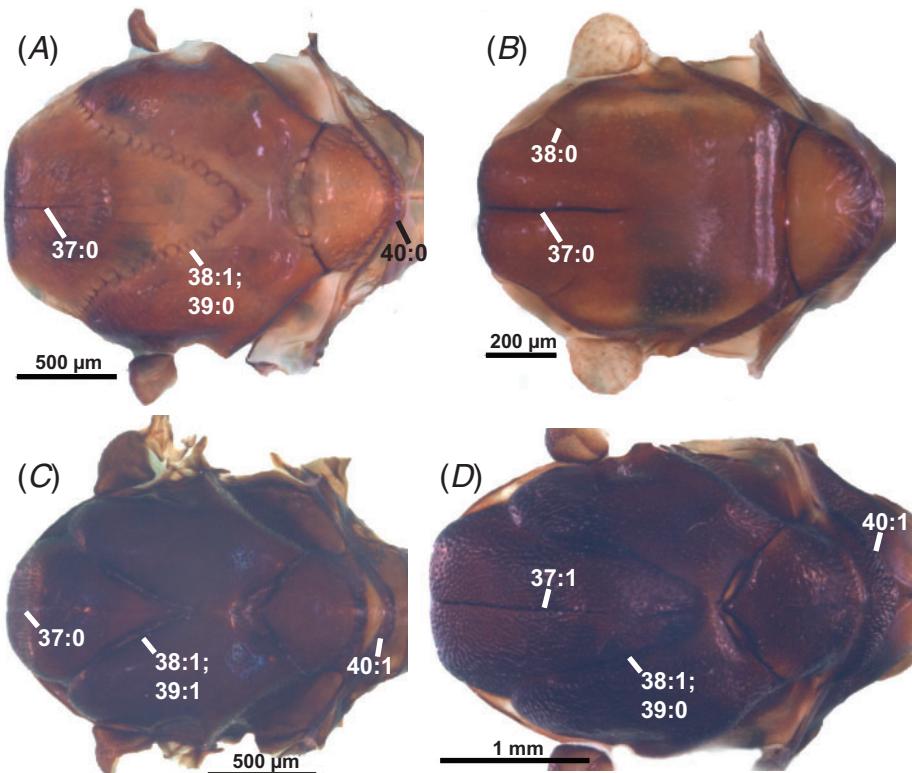

**Fig. 4.** Lateral view of pronotum and mesothorax of: (A) *Arge ustulata* (Linné, 1758) (Argidae, Arginae); (B) *Eriocampa ovata* (Linné, 1760) (Tenthredinidae, Allantinae); (C) *Rocalia japonica* Naito, 1988 (Tenthredinidae, Selandriinae); (D) *Stethomostus fuliginosus* (Schrank, 1781) (Tenthredinidae, Blennocampinae); (E) *Craterocercus fraternalis* (Norton, 1872) (Tenthredinidae, Nematinae); (F) *Dolerus nitens* Zaddach, 1859 (Tenthredinidae, Selandriinae). Character states indicated by numbers.

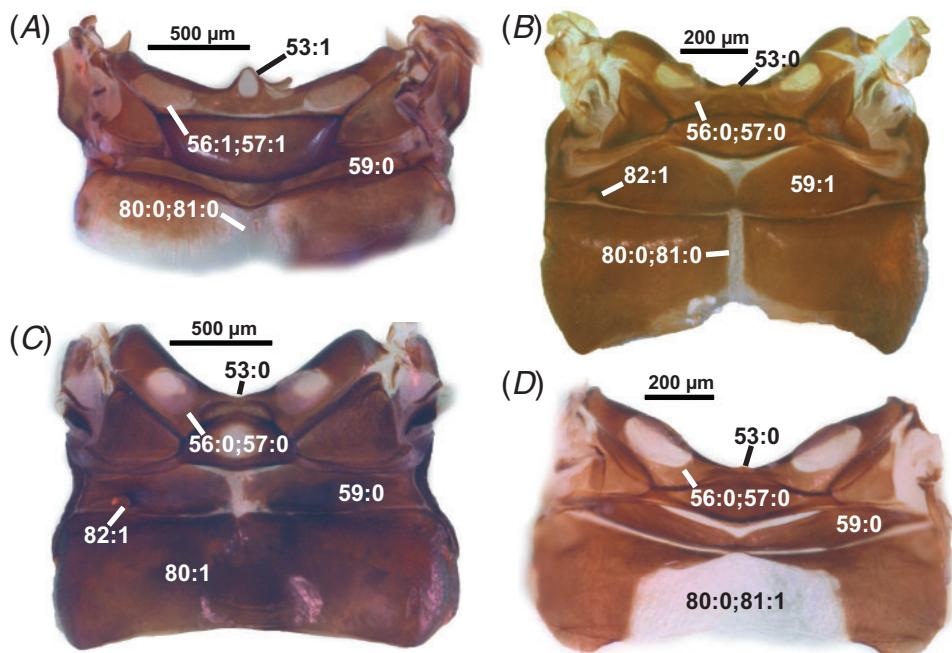

**Fig. 5.** Lateral view of propectus of (A) *Blasticotoma filiceti* Klug, 1834 (Blasticotomidae); (B) *Lophyrotoma analis* (Costa, 1864) (Pergidae, Pteryperginae); (C) *Nematus caeruleocarpus* Hartig, 1837 (Tenthredinidae, Nematinae); (D) *Dolerus nitens* Zaddach, 1859 (Tenthredinidae, Selandriinae). Character states indicated by numbers.

**Fig. 6.** Ventral view of propectus of: (A) *Abia fasciata* (Linné, 1758) (Cimbicidae, Abiinae); (B) *Blasticotoma filiceti* Klug, 1834 (Blasticotomidae); (C) *Heteroperreyia hubrichi* Malaise, 1955 (Pergidae, Perreyinae); (D) *Allantus cinctus* (Linné, 1758) (Tenthredinidae, Allantinae). Character states indicated by numbers.

**Fig. 7.** Dorsal view of mesonotum in: (A) *Aproceros leucopoda* Takeuchi, 1939 (Argidae, Sterictiphorinae); (B) *Arcodulecera dorsalis* Say, 1836 (Pergidae, Acordulecerinae); (C) *Ametastegia glabrata* (Fallén, 1808) (Tenthredinidae, Allantinae); (D) *Nematus caeruleoecampus* Hartig, 1837 (Tenthredinidae, Nematinae). Character states indicated by numbers.

**Fig. 8.** Dorsal view of metanotum in: (A) *Lophyrotoma analis* (Costa, 1864) (Pergidae, Pteryperginae); (B) *Ametastegia pallipes* (Spinola, 1808) (Tenthredinidae, Allantinae); (C) *Tenthredopsis ornata* (Serville, 1823) (Tenthredinidae, Tenthredininae); (D) *Hoplocampa* sp. (Tenthredinidae, Nematinae). Character states indicated by numbers.

slides in Entellan (Merck KGaA, Darmstadt, Germany) and examined in a Leitz compound microscope. Images of specimens in glycerin were taken with a Leica DFC 450C digital camera mounted on a Leica MZ 16A dissecting microscope (Leica Microsystems). Wings were temporarily mounted on slides in glycerin during imaging. Compound images were compiled from image stacks with Zerene Stacker (Zerene Systems, Richland, WA, USA). Final images were cleaned up in Adobe Photoshop before being assembled into plates with Adobe Illustrator (Adobe Systems, San Jose, CA, USA). Cladograms reproduced were exported as PDFs from Mesquite, and modified in Adobe Photoshop and Illustrator.

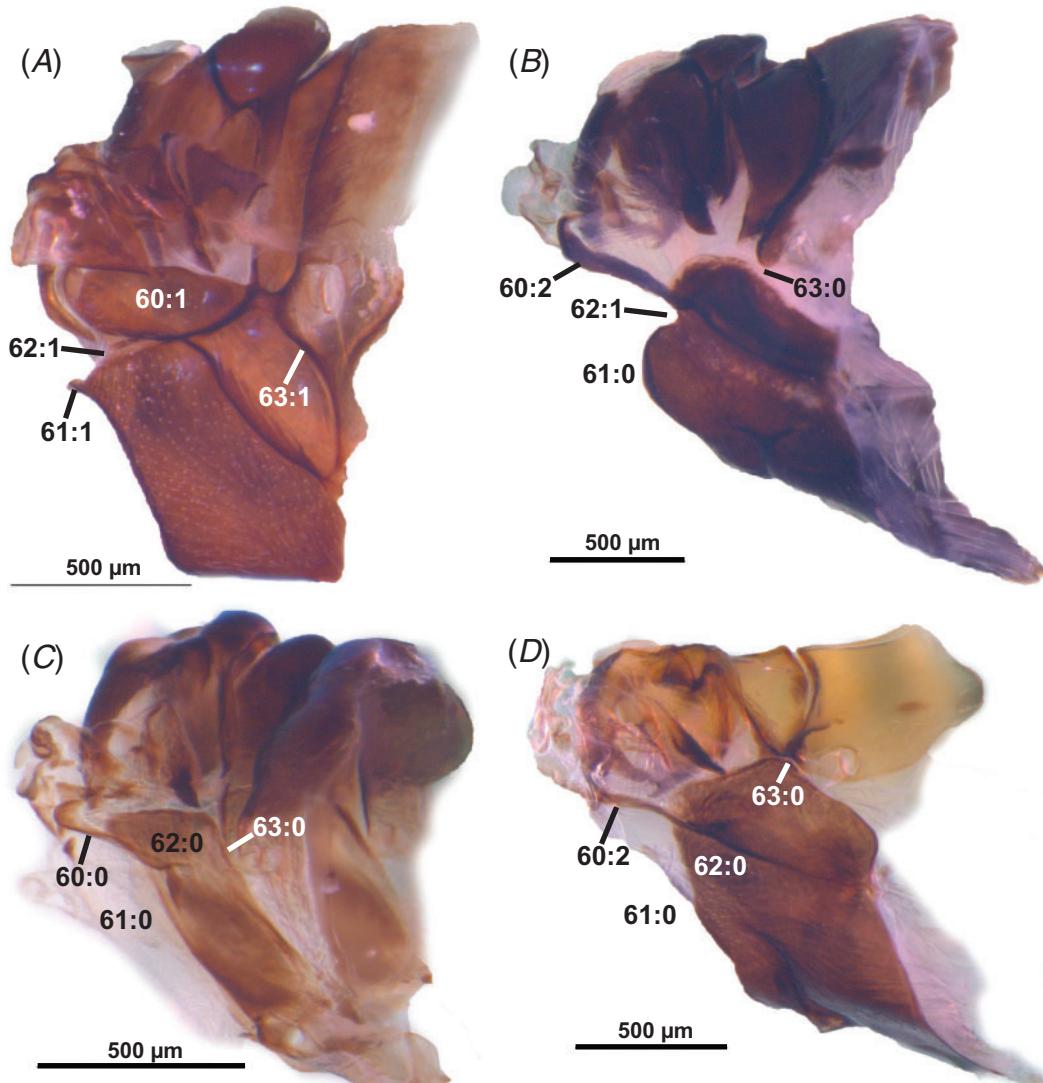

#### Phylogenetic analyses

The character matrix (see Table 1) was assembled in Mesquite 2.75 (Maddison and Maddison 2011). The dataset was

analysed with TNT 1.1. (Goloboff *et al.* 2008). The following characters were treated as ordered: 9, 11, 13, 18, 25, 56, 84, 94, 103, 104, 124–128, 130, 131, 136, 144. Space for 1 000 000 trees was reserved in memory. Traditional searches were run for equal and implied weights analyses with 10 000 replications, saving 100 trees per replication. The root was *Macroxyela*. K values for implied weights analyses were set to 1–15, 20, 25 and 30 in turn. Character evolution was explored in Mesquite.

#### Character list

The character list is presented in Table 2. Many of the characters examined here are extracted and modified from previous studies conducted in a phylogenetic context: head and mouthparts (Vilhelmsen 1996, 1999, 2011), thorax (Vilhelmsen 2000a, 2000b) and ovipositor system

**Fig. 9.** Lateral view of metathorax in: (A) *Lophyrotoma analis* (Costa, 1864) (Pergidae, Pteryperginae); (B) *Eopsis beaumonti* Benson, 1959 (Tenthredinidae, Allantinae); (C) *Heterarthrus vagans* (Fallén, 1808) (Tenthredinidae, Heterarthrinae); (D) *Leucopelmonus annulicornis* (Harrington, 1893) (Tenthredinidae, Tenthredininae). Character states indicated by numbers.

(Vilhelmsen 2000c; Weltz and Vilhelmsen 2014). Other sources of characters are some of the existing comprehensive keys for ‘Symphyta’: Benson (1952, 1958), Goulet (1992) and Zhelokhovtsev *et al.* (1994). The male genitalia of the basal Hymenoptera were examined by Schulmeister (2001, 2003b), but this character system falls outside the scope of the present contribution, as do characters from larval anatomy (Yuasa 1922; Maxwell 1955). Previous compilations of morphological characters relevant for tenthredinoid relationships are found in Vilhelmsen (2001) and Schulmeister (2003c).

## Results and discussion

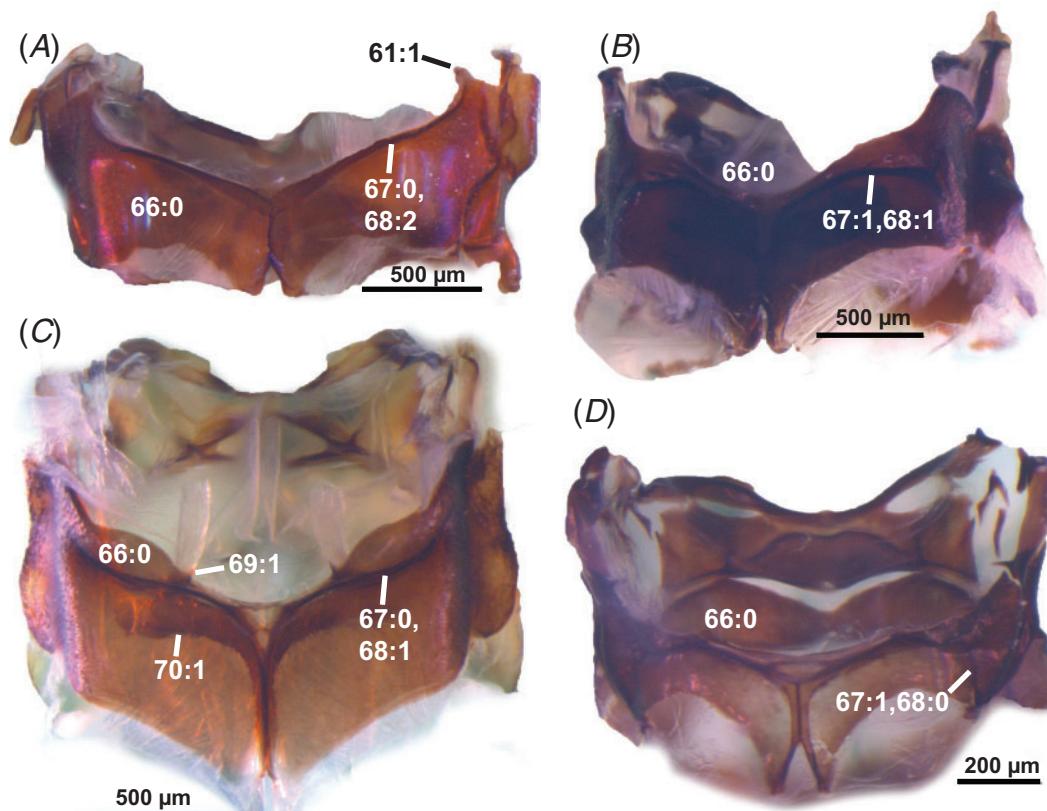

The equal weights (EW; Fig. 14) analysis produced 3628 trees of length 1448 steps. The shortest trees were retrieved only in very few replications. Resolution was generally poor, the base of the Tenthredinoidea s. str. forming a large polytomy. The only major clades supported were the Nematinae and a clade comprising Diprionidae + (Cimbicidae + (Argidae + Pergidae)).

The implied weights analyses (IW) usually produced only one tree (Figs 15, 16); however, the topology of the tree differed substantially according to the *k* value implemented, and the most fit tree was only retrieved in very few replications. The deeper relationships especially were highly

unstable, but subfamilies and even in some cases genera (e.g. *Allantus*, *Cladius*, *Dolerus*) within Tenthredinidae were not supported in most analyses. In the following, only the relationships that could be observed across a substantial range of analytical settings are discussed.

Blasticotomidae and Tenthredinoidea s. str. were always monophyletic and sister groups. The families Argidae, Cimbicidae, Diprionidae and Pergidae were always monophyletic, Cimbicidae+(Argidae+Pergidae) always coming out as a clade (CAP in Figs 14–16). Diprionidae was the sister to this clade in the EW and IW analyses with *k*>12 (Fig. 16). However, when *k* was 1–12, Diprionidae was placed inside the Nematinae (Fig. 15), as sister to *Cladius pectinicornis*. ‘Tenthredinidae’ was never monophyletic, Argidae, Cimbicidae, Diprionidae and Pergidae always being nested inside.

The shifting position of the Diprionidae was intriguing. The position within Nematinae, even within the genus *Cladius*, is supported by several putative synapomorphies: presence of lateral projections on the male antennae (char. 10:1; only shared with *Cladius pectinicornis* and two pergids), anterior fore tibial spur simple (char. 34:0), and well developed ctenidia laterally and ventrally displaced aulax medially on first valvula (chars 134:1 and 136:2; see also Weltz and Vilhelmsen 2014). However, the alternative position as sister to Cimbicidae+(Argidae+Pergidae) would be supported by the

**Fig. 10.** Ventral view of metathorax in: (A) *Lophyrotoma analis* (Costa, 1864) (Pergidae, Pteryperginae); (B) *Eopsis beaumonti* Benson, 1959 (Tenthredinidae, Allantinae); (C) *Leucopelmonus annulicornis* (Harrington, 1893) (Tenthredinidae, Tenthredininae); (D) *Notofenusu surosa* (Konow, 1905) (Tenthredinidae, Heterarthrinae). Character states indicated by numbers.

cenchrus configuration (chars 56:2, 57:1) and ovipositor characters (chars 133:1, 140:0). Furthermore, no analyses including molecular data have placed Diprionidae inside Nematinae (Schulmeister 2003a; Nyman *et al.* 2006; Ronquist *et al.* 2012; Boevé *et al.* 2013; Malm and Nyman 2015).

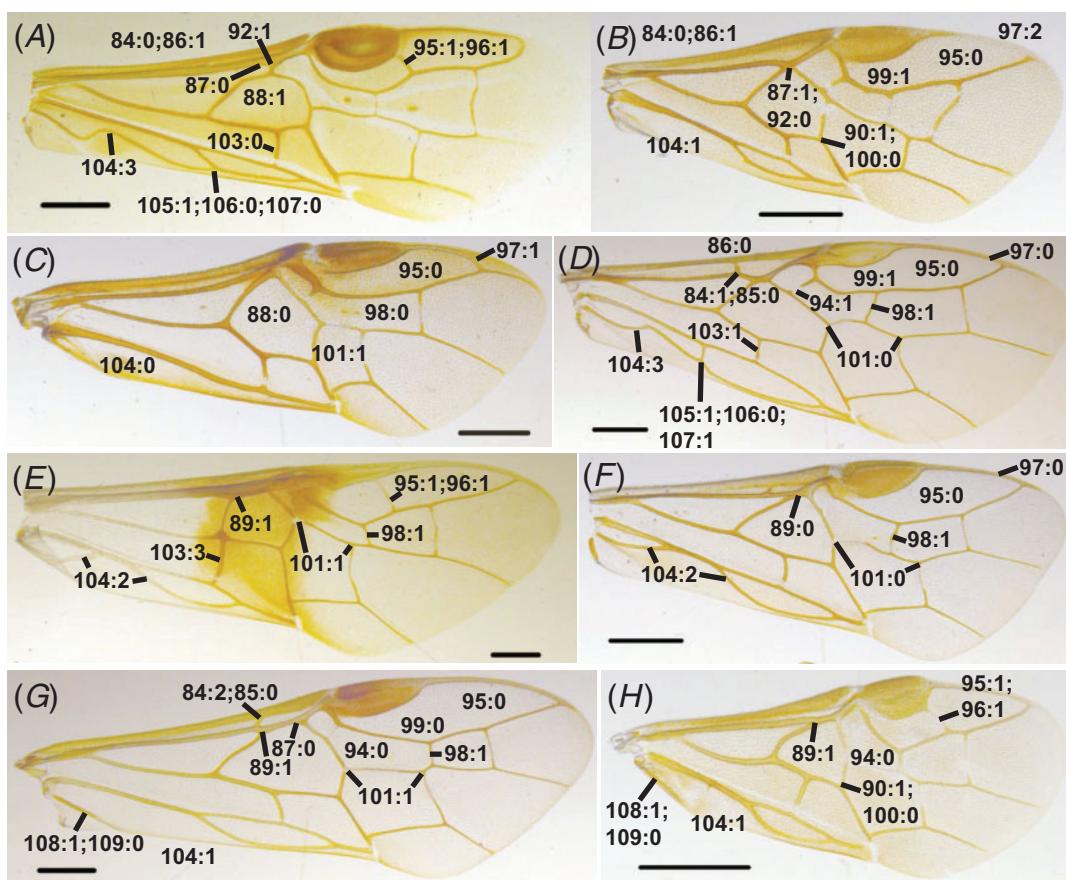

The Cimbicidae are always placed as the sister to Argidae + Pergidae, supported by the fusion between the first abdominal tergum and the metapleuron (char. 63:1), the absence of the posteroventral apodeme for the posterior pleuro-furcal muscle (char. 65:0; probably correlated with 63:1), the first abdominal tergum not being subdivided medially (80:1; reversed in some argids and pergid), and the absence of the anterior branch of the subcosta and the costal cell being short (chars 84:0 and 86:1; likely also correlated). Most other analyses place Cimbicidae in a clade with Diprionidae and Tenthredinidae, often as sister to Diprionidae (Schulmeister 2003a; Nyman *et al.* 2006; Malm and Nyman 2015). Apparently there is support for this relationship from the molecular but also some morphological data, e.g. male genitalia (Schulmeister 2003b).

Allantinae were never monophyletic, the majority of the taxa usually coming out at the base of Tenthredinoidea s. str. in

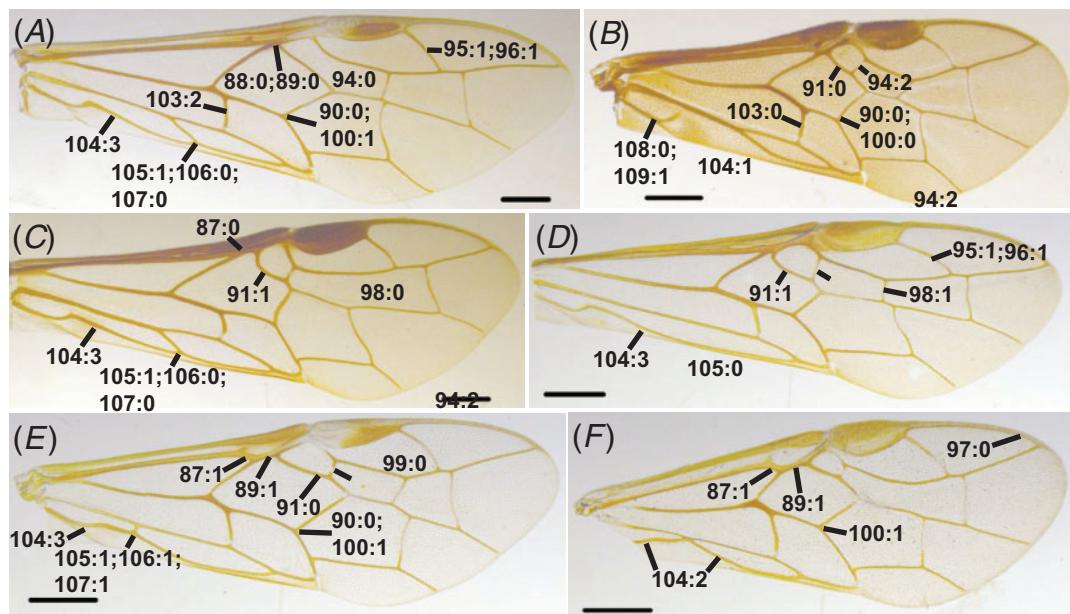

one or two larger clades (often including non-allantines), but always with some taxa scattered across the phylogeny. *Harpiphorus* was sister to all other Tenthredinoidea s. str. in all IW analyses (Figs 15, 16). *Athalia* is a rogue taxon, usually falling outside major clades. At  $k > 7$  and EW, *Athalia* is sister to *Eriocampa*. Recent comprehensive molecular analyses have placed *Athalia* as sister to all other Tenthredinidae (Boevé *et al.* 2013) or all except Heptamelini (Malm and Nyman 2015).

Blennocampinae was never monophyletic, but usually scattered across the phylogeny as small clades or grades. Indeed, in the most comprehensive identification manuals (Benson 1952; Goulet 1992) this subfamily is among the last to key out and is mainly characterised by not having the characters used to delimit the other subfamilies. In Boevé *et al.* (2013) blennocampines are mixed with allantine and heterarthrine taxa; in Malm and Nyman (2015) the subfamily is paraphyletic with respect to Heterarthrinae and the allantine *Eusunoxa*. Blennocampinae seems to be something of a taxonomic waste basket.

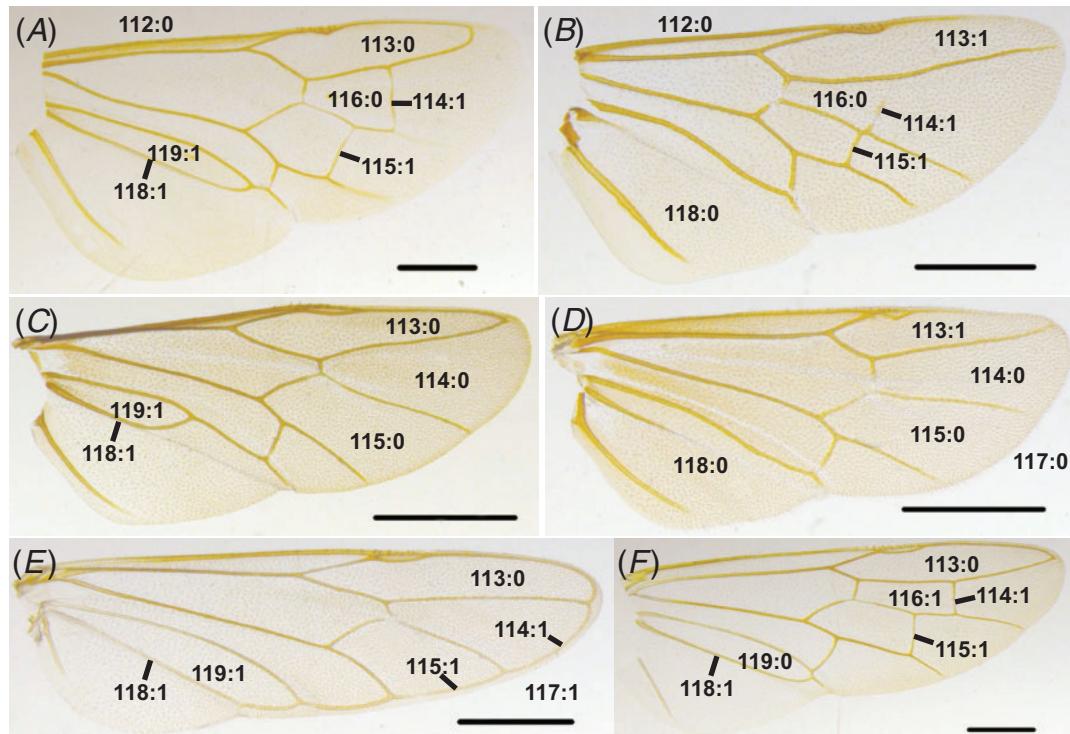

The Heterarthrinae were never retrieved as monophyletic. A core clade comprising *Fenusia*, *Heterarthrus*, *Metallus*,

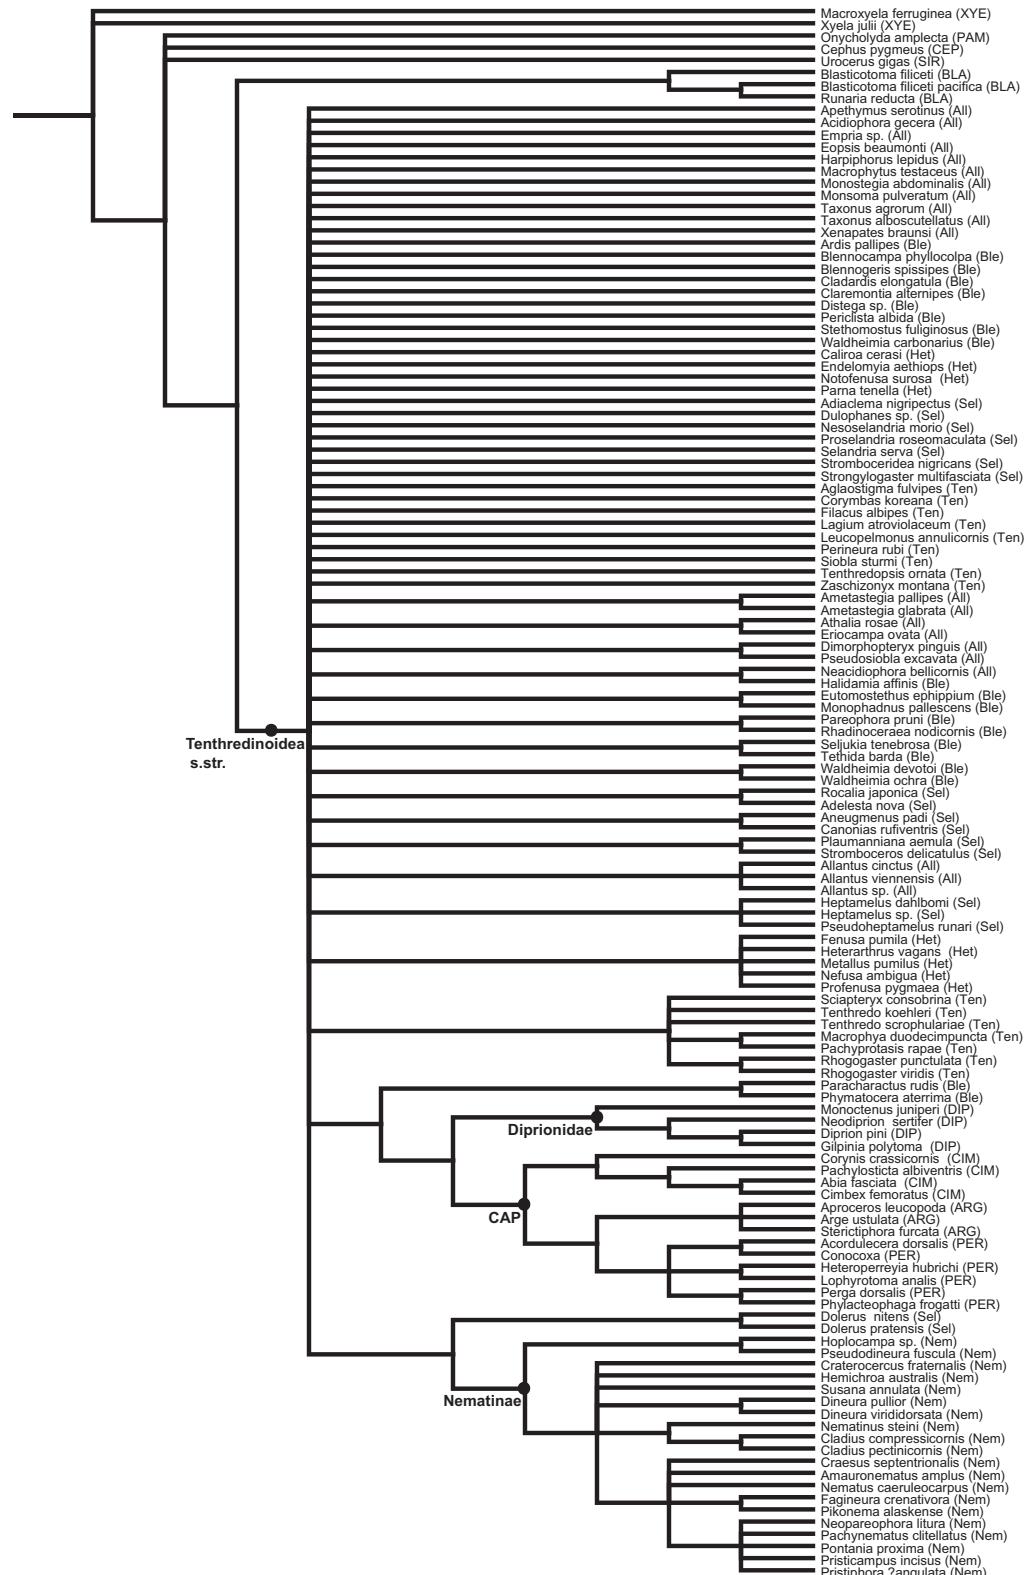

**Fig. 11.** Forewing of: (A) *Blasticotoma filiceti* Klug, 1834 (Blasticotomidae); (B) *Aproceros leucopoda* Takeuchi, 1939 (Argidae, Sterictiphorinae); (C) *Lophyrotoma analis* (Costa, 1864) (Pergidae, Pteryperginiae); (D) *Neodiprion sertifer* (Geoffroy, 1785) (Diprionidae, Diprioninae); (E) *Abia fasciata* (Linné, 1758) (Cimbicidae, Abiinae); (F) *Cladus pectinicornis* (Geoffroy, 1785) (Tenthredinidae, Nematinae); (G) *Nematus caeruleoecarpus* Hartig. 1837 (Tenthredinidae, Nematinae); (H) *Profenusia pygmaea* (Klug, 1816) (Tenthredinidae, Heterarthrinae). All scales 1 mm.

Abbreviations: All, Allantinae; ARG, Argidae; BLA, Blasticotomidae; Ble, Blennocampinae; CAP, Cimbicidae-Argidae-Pergidae clade; CEP, Cephidae; CIM, Cimbicidae; DIP, Diprionidae; Het, Heterarthrinae; Nem, Nematinae; PAM, Pamphiliidae; PER, Pergidae; Sel, Selandrinae; SIR, Siricidae; Ten, Tenthredininae; XYE, Xyelidae.

**Fig. 15.** Most fit tree of fit 57.52315, obtained by implied weights analysis with concavity constant  $k = 10$ . Abbreviations as in Fig. 14. Subfamilies in Tenthredinidae colour-coded: Allantinae, yellow; Blennocampinae, red; Heterarthrinae, green; Nematinae, orange; Selandrinae, blue; Tenthredininae, violet.

**Fig. 16.** Most fit tree of fit 38.94650, obtained by implied weights analysis with concavity constant  $k = 20$ . Abbreviations as in Fig. 14. Subfamilies in Tenthredinidae colour-coded: Allantinae, yellow; Blennocampinae, red; Heterarthrinae, green; Nematinae, orange; Selandrinae, blue; Tenthredininae, violet.

*Nefusa*, *Parna* and *Profenus* was supported under IW with  $k=8-15$ , 20 or 25 (Fig. 15). *Notofenus* was included in this group with  $k=11-15$ , 20 or 25 (Fig. 16). The core Heterarthrinae corresponds to the ‘true leafminers’ or Heterarthrinae s. str., which was also recovered by Leppänen *et al.* (2012) and Malm and Nyman (2015). In both these analyses, as in the present, the closest relatives of this clade are blennocampine taxa. The Heterarthrinae s. str. are supported by having the tarsal claws simple (char. 78:0; also in *Caliroa*), and having forewing veins m and 1m-cu converging (char. 90:1; also in *Caliroa* and *Endelomyia*). The remaining Heterarthrinae s. lat. included (*Caliroa*, *Endelomyia*) behave as rogue taxa. None of the two molecular analyses placed them with Heterarthrinae s.str. Indeed, their larvae are not leafminers, but external feeders that skeletonise the leaves of their host plants, leaving only the veins (Leppänen *et al.* 2012).

A clade comprising Nematinae with the Diprionidae nested inside was retrieved under IW with  $k$  values 4–12; when  $k=1-3$ , 20, 25; *Hoplocampa* was removed from the other Nematinae. The Nematinae were monophyletic under IW with  $k=12-15$ , 30 and under EW, in the latter case having *Dolerus* as their sister group (Fig. 14). The core Nematinae (all except *Hoplocampa* and *Pseudodineura*) are supported by the following characters: forewing Rs to 2r-m distance longer than 2r-m to 3r-m distance (char. 99:0), the presence of extensions on the anterolateral corners of the female eighth abdominal tergum and the elongate cerci (char. 124:1, changing to 124:2 within Nematinae). Interestingly, some of the published analyses with the largest sample of Nematinae (Nyman *et al.* 2006, 2010) have *Hoplocampa* as the sister to all other Nematinae in at least some analyses. Furthermore, there is good correspondence between the molecular and morphological topologies for the subfamily, the ‘lower’ genera included in both samples (*Cladius*, *Craterocercus*, *Dineura*, *Hemichroa* and *Susana*) branching off basally (Figs 15, 16).

The Selandriinae were never monophyletic. *Adelesta* was a rogue taxon always placed outside Selandriinae, often as sister to the majority of Tenthredininae (Fig. 15). Under IW with  $k=5-6$  and 13–15, almost all Selandriinae came out together, with Heptamelini (*Heptamelus* + *Pseudoheptamelus*) as sister to the rest. Under IW with  $k=1-4$  and 7–12, the Heptamelini fell outside Selandriinae, as did *Dolerus* at  $k=20$ , 25, 30. The core Selandriinae (excluding *Adelesta*, *Dolerus* and Heptamelini) were supported by having the anterodorsal part of the mesopleuron raised (char. 43:1) and having the forewing cross vein 1a absent (char. 105:0). The inclusion of *Dolerus* as sister to this clade (Fig. 15) was supported by the proximal part of the forewing vein Rs+M being strongly recurved, the main character used to define the Selandriinae (e.g. Benson 1952). Heptamelini was always retrieved, even in the EW analyses (Fig. 14), supported by the presence of 5–8 antennomeres (char. 9:2) and with the anterior fore tibial spur simple (char. 34:0).

*Dolerus* was retrieved as sister to the core Selandriinae by Malm and Nyman (2015), whereas Boevé *et al.* (2013) and Isaka and Sato (2014) put the genus inside the core Selandriinae; *Dolerus* has previously been placed in its own subfamily, the Dolerinae. Both Boevé *et al.* (2013) and Malm and Nyman (2015) placed Heptamelini outside Selandriinae,

as the sister to all Tenthredinidae except *Athalia*, or sister to the remaining Tenthredinidae + (Cimbicidae + Diprionidae), respectively. Isaka and Sato (2014) did not include any members of this tribe. Malm and Nyman (2015) suggested the Heptamelini should be raised to family status. The morphological evidence supports that at least it should be excluded from Selandriinae.

The Tenthredininae were only monophyletic under IW with  $k=14$ , 15, with *Corymbas* and *Siobla* basal. *Siobla* was a rogue taxon and fell well outside the subfamily when  $k=1-13$ , 20, 25 or 30, *Corymbas* was also outside when  $k=7-13$ , these two taxa being sisters (Fig. 15). *Siobla* was placed as sister to all other Tenthredininae by Malm and Nyman (2015), but outside the subfamily by Boevé *et al.* (2013). However, the remaining Tenthredininae were retrieved in all IW analyses of the morphological data. These core Tenthredininae were supported by having the posterior thoracic spiracle concealed by the posterodorsal part of the mesopleuron (char. 44:1), with forewing vein R bent at cell 1M (87:1; both these characters are also present in *Corymbas* and *Siobla*), and forewing Rs to 2r-m distance longer than 2r-m to 3r-m (char. 99:0).

## Conclusions

The results of the analyses of the present dataset were satisfactory in the sense that they corroborate previously well established clades (i.e. Tenthredinoidea, Tenthredinoidea s. str., Argidae + Pergidae, all families except Tenthredinidae, which has rarely been retrieved as monophyletic in recent analyses, e.g. Boevé *et al.* 2013). However, they failed to deliver well supported relationships at the subfamily level within Tenthredinidae, despite the dataset being designed to test the existing classification of the ‘family’. This is in contrast to Malm and Nyman (2015), who produced a more robust phylogeny and recovered several of the tenthredinid subfamilies.

The failure to obtain a robust phylogenetic hypothesis with the morphological dataset assembled here might be partly because not enough characters were included relative to the comparatively high number of terminals scored. The ratio of characters (146) to terminals (129) was only slightly above 1, which is apparently insufficient to obtain well resolved and supported relationships. However, the inability to recover the existing subfamily classification was probably also caused by inherent problems with the delimitation of at least some of the subfamilies, as indicated by the results of Malm and Nyman (2015).

To make further progress with the phylogenetics and classification of the Tenthredinidae, it is necessary to explore additional data sources, e.g. morphology of the male genitalia and larvae, as well as molecular markers in addition to those already employed by Malm and Nyman (2015), and analyse all the data together. It is very likely that apart from redefining boundaries of the existing subfamilies, new taxa at this and even the family level will have to be recognised eventually. Indeed, Malm and Nyman (2015) suggested raising the Heptamelini to family rank, given they were consistently placed as sister to all other Tenthredinidae + (Cimbicidae + Diprionidae). Likewise, Boevé *et al.* (2013) found support for elevating *Athalia* to at least subfamily rank. Future combined analyses will hopefully

provide a solid foundation for tenthredinid classification, as well as allow the exploration of the evolutionary history of the family.

## Acknowledgements

Stephan Blank, Georg Goergen, Henri Goulet, Tikahika Naito, Tommi Nyman, Jan Pedersen, Ladislav Roller, Dave Smith and Veli Vikberg provided invaluable material for this study. Gavin Broad and Lars Krogmann provided helpful comments on an earlier version of the paper.
